## Loading the Image Dataset

Given the directory structure where each subfolder represents a class and contains `.jpg` image files, the `tensorflow.keras.utils.image_dataset_from_directory` utility is an ideal choice for loading this dataset. This function will automatically infer class labels from the subdirectory names, resize images to a uniform size (which is crucial for consistent analysis and model input), and split the data into training and validation sets.

First, we will define some parameters like image dimensions and batch size. Then, we will load the dataset using the specified path.

```python
import tensorflow as tf

# Define image dimensions and batch size
IMG_HEIGHT = 224  # Standard size for many pre-trained models
IMG_WIDTH = 224
BATCH_SIZE = 32

# Load the dataset using image_dataset_from_directory
# Set validation_split to create a small validation set
# Set subset to 'training' for the training set and 'validation' for
the validation set
# seed is for reproducibility
train_ds = tf.keras.utils.image_dataset_from_directory(
    dataset_path,
    validation_split=0.2,
    subset="training",
    seed=123,
    image_size=(IMG_HEIGHT, IMG_WIDTH),
    batch_size=BATCH_SIZE
)

val_ds = tf.keras.utils.image_dataset_from_directory(
    dataset_path,
    validation_split=0.2,
    subset="validation",
    seed=123,
    image_size=(IMG_HEIGHT, IMG_WIDTH),
    batch_size=BATCH_SIZE
)

# Print information about the loaded datasets
print(f"\nNumber of training batches:
{tf.data.experimental.cardinality(train_ds)}")
print(f"Number of validation batches:
{tf.data.experimental.cardinality(val_ds)}")

# Get class names
class_names = train_ds.class_names
print(f"Class names: {class_names}")
print(f"Number of classes: {len(class_names)}")
```

```
Found 5224 files belonging to 80 classes.
Using 4180 files for training.

    plt.show()

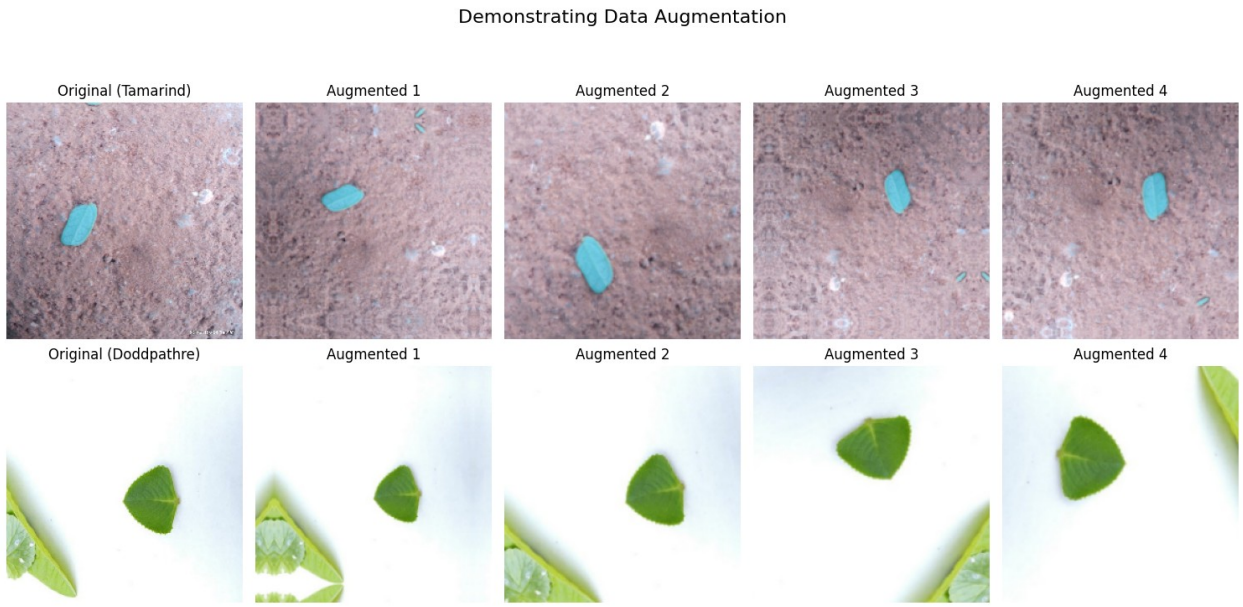
print("Demonstrated data augmentation on sample images.")
```



```
Demonstrated data augmentation on sample images.
```

# Generate Data Visualizations

## Subtask:

Generate a visualization showing the average image for several classes in the dataset.

```
import numpy as np
import matplotlib.pyplot as plt

# 1. Initialize dictionaries
# class_sums will store the sum of pixel values for each class
# class_counts will store the number of images for each class
class_sums = {class_id: np.zeros((IMG_HEIGHT, IMG_WIDTH, 3),
dtype=np.float32) for class_id in range(len(class_names))}
class_counts = {class_id: 0 for class_id in range(len(class_names))}

# 2. Iterate through the train_ds dataset
# 3. For each image, convert to NumPy, normalize, add to sum,
increment count
for images, labels in train_ds.unbatch().as_numpy_iterator():
    # Unbatching already handles individual images and labels
    class_id = labels
    image_np = images.astype(np.float32) / 255.0 # Normalize pixel
values to [0, 1]
```

```
    class_sums[class_id] += image_np
    class_counts[class_id] += 1

# 4. Calculate the average image for each class
average_images = {}
for class_id, count in class_counts.items():
    if count > 0:
        average_images[class_id] = class_sums[class_id] / count
    else:
        print(f"Warning: Class {class_names[class_id]} has no samples
in the training dataset.")

# 5. Select a few representative classes and display their average
images
# Choosing a few classes to display - you can modify this list
sample_class_indices = [class_names.index('Turmeric'),
class_names.index('Tulsi'), class_names.index('Mango'),

```
Generated and displayed average images for selected classes.
```

# Analyze class distribution in validation dataset

## Subtask:

Analyze and visualize the class distribution in the validation dataset (`val_ds`) to understand how classes are distributed across the training and validation splits, especially in light of the missing classes observed in `train_ds`.

**Reasoning**: To analyze the class distribution in the validation dataset, I will initialize a Counter, iterate through the `val_ds` to count class occurrences, map class indices to names, print the distribution, and then visualize it using a bar chart with proper labels and titles.

```
from collections import Counter
import matplotlib.pyplot as plt

# 1. Initialize a Counter object for validation dataset
val_class_counts = Counter()

# 2. Iterate through the val_ds dataset, unbatching it
for _, labels in val_ds.unbatch():
    # 3. For each label, increment its count
    val_class_counts[labels.numpy()] += 1

# 4. Map class indices to class names for better readability
val_class_distribution = {class_names[idx]: count for idx, count in
sorted(val_class_counts.items())}

# 5. Print the class distribution
print("\nClass Distribution in Validation Dataset:")
for class_name, count in val_class_distribution.items():
    print(f"{class_name}: {count}")

# 6. Create a bar chart visualization of the class distribution
plt.figure(figsize=(20, 8)) # 7. Adjust figure size
plt.bar(val_class_distribution.keys(),
val_class_distribution.values(), color='lightcoral')
plt.xlabel('Class Name')
plt.ylabel('Number of Images')
plt.title('Distribution of Classes in Validation Dataset')
plt.xticks(rotation=90, fontsize=10) # Rotate x-axis labels
plt.tight_layout() # Adjust layout for optimal display
plt.show()

print("Displayed bar chart of class distribution in the validation
dataset.")
```

# Reflect on Visualizations and Insights

## Subtask:

Analyze the generated visualizations, reflect on their impact, and describe any insights gained. Suggest potential improvements for future visualizations or analysis, aligning with the project's requirements.

# Summary:

## Data Analysis Key Findings

- The dataset located at `/content/gdrive/MyDrive/Medicinal Leaf dataset` is an image dataset containing 5224 files across 80 distinct medicinal leaf classes.
- The `tensorflow.keras.utils.image_dataset_from_directory` utility was successfully used to load the dataset, splitting it into training (4180 files) and validation (1044 files) sets with an 80/20 ratio.
- Initial exploration revealed a significant class imbalance in the training dataset; for instance, 'Lantana' had only 1 sample, 'camphor' had 2 samples, while 'Tulsi' had 141 samples and 'Tamarind' had 140 samples.
- Data augmentation techniques such as horizontal/vertical flipping, rotation (up to 0.2), and zooming (up to 0.2) were successfully demonstrated on sample images, showing their potential to generate diverse training examples.
- During the calculation of average images per class, it was discovered that several classes (e.g., 'Coffee', 'Ganigale', 'Kohlrabi', 'Nooni', 'Palak(Spinach)', 'Rose') had no samples present in the training dataset (`train_ds`), indicating an inconsistency or data distribution issue.

- The class distribution in the validation dataset (`val_ds`) also exhibited imbalance, with some classes having very low counts (e.g., 'Bringaraja' with 1 sample, 'Lantana' with 2 samples) and others being well-represented (e.g., 'Curry' with 44 samples, 'Tamarind' with 36 samples).

### Insights or Next Steps

- Address the observed class imbalance in both training and validation sets. Strategies like weighted loss functions, oversampling minority classes (potentially using more aggressive augmentation for them), or undersampling majority classes should be considered.
- Investigate the discrepancy regarding classes missing from the training dataset. This could involve re-evaluating the `validation_split` method, checking the dataset's integrity, or re-running the dataset loading process to ensure all classes are properly distributed across splits.

# Task

Convert the `train_ds` and `val_ds` TensorFlow datasets into NumPy arrays for images and their corresponding labels.

## Convert Datasets to NumPy Arrays

### Subtask:

Convert the `train_ds` and `val_ds` TensorFlow datasets into NumPy arrays for images and their corresponding labels.

```
import numpy as np
import tensorflow as tf

# Re-define dataset_path if not already in scope (from cell c01baf02)

# Extract Texture Features

## Subtask:

Implement code to extract texture-based features (e.g., Gray-Level Co-occurrence Matrix (GLCM) features, Local Binary Patterns (LBP)) from the images.

```
from skimage.feature import graycomatrix, graycoprops
from skimage.color import rgb2gray
import numpy as np

# 1. Define the function to extract texture features
def extract_texture_features(image):
    # Ensure image is in float for rgb2gray
    image_float = image.astype(float) / 255.0

    # 2. Convert RGB image to grayscale
    gray_image = rgb2gray(image_float)

    # Normalize grayscale image to 0-255 for GLCM (needs uint8 for
graycomatrix)
    # And ensure it's 2D
    gray_image_256 = (gray_image * 255).astype(np.uint8)

    # 3. Compute GLCM
    distances = [1] # Distance 1
    angles = [0, np.pi/4, np.pi/2, 3*np.pi/4] # 0, 45, 90, 135 degrees

    # GLCM expects images with pixel values up to 255 (or specified
levels)
    # and works on 2D arrays.
    # Using levels=256 ensures full range is considered.
    glcm = graycomatrix(gray_image_256, distances=distances,
angles=angles, levels=256, symmetric=True, normed=True)

    # 4. Calculate texture properties from GLCM
    properties = ['contrast', 'dissimilarity', 'homogeneity',
```

```
'energy', 'correlation', 'ASM']
    texture_features = []
    for prop in properties:
        texture_features.extend(graycoprops(glcm, prop).flatten())

    return np.array(texture_features)

# 5. Apply the function to each image in train_images
print("Extracting texture features from training images...")
# train_images are already available from the previous step
# train_images = np.load('train_images.npy') # If running
independently
# val_images = np.load('val_images.npy') # If running independently

```

# Extract Shape Features

## Subtask:

Implement code to extract shape-based features (e.g., contour-based metrics like area, perimeter, aspect ratio, solidity, eccentricity) from the images.

**Reasoning**: To extract shape features from the images, I will define a function that converts images to grayscale, applies thresholding to find contours, selects the largest contour, and then calculates various shape properties like area, perimeter, aspect ratio, solidity, and eccentricity, finally applying this function to both the training and validation image arrays.

```
import cv2
import numpy as np

# 1. Define the function to extract shape features
def extract_shape_features(image):
```

```
    # Ensure image is in uint8 format for OpenCV operations
    # The images are already in a 0-255 range from
`image_dataset_from_directory`
    image_uint8 = image.astype(np.uint8)

    # 2. Convert RGB image to grayscale
    gray_image = cv2.cvtColor(image_uint8, cv2.COLOR_RGB2GRAY)

    # 3. Apply Otsu's thresholding to obtain a binary mask
    # Ensure 255 is the max_value for binary thresholding
    _, binary_mask = cv2.threshold(gray_image, 0, 255,
cv2.THRESH_BINARY + cv2.THRESH_OTSU)

    # 4. Find contours in the binary mask
    contours, _ = cv2.findContours(binary_mask, cv2.RETR_EXTERNAL,
cv2.CHAIN_APPROX_SIMPLE)

    # Initialize shape features with zeros/NaNa in case no contour is
found
    area, perimeter, aspect_ratio, solidity, eccentricity = 0.0, 0.0,
0.0, 0.0, 0.0

    if contours:
        # 5. Select the largest contour
        largest_contour = max(contours, key=cv2.contourArea)

        # 6. Calculate shape properties for the selected contour
        area = cv2.contourArea(largest_contour)
        perimeter = cv2.arcLength(largest_contour, True)

        # Bounding Rectangle
        x, y, w, h = cv2.boundingRect(largest_contour)
        if h != 0: # Avoid division by zero
            aspect_ratio = float(w) / h

        # Solidity
        hull = cv2.convexHull(largest_contour)
        hull_area = cv2.contourArea(hull)
        if hull_area != 0: # Avoid division by zero
            solidity = float(area) / hull_area

        # Eccentricity (from fitting an ellipse)
        # Requires at least 5 points for fitEllipse
        if len(largest_contour) >= 5:
            (x, y), (MA, ma), angle = cv2.fitEllipse(largest_contour)
            # Major axis (ma) and Minor axis (MA) lengths are already
provided
            # If ma (major axis) is not zero (to avoid division by
zero)
            if ma != 0:
```

```
                eccentricity = np.sqrt(1 - (MA / ma)**2) # (minor_axis
/ major_axis)**2

    # 7. Return these calculated shape features as a NumPy array
    # Ensure all features are float and concatenated
    return np.array([area, perimeter, aspect_ratio, solidity,
eccentricity], dtype=np.float32)

# 8. Apply the function to each image in train_images
print("Extracting shape features from training images...")

# Combine Feature Vectors

## Subtask:

Concatenate all the extracted features (color, texture, and shape) into a single, comprehensive feature vector for each image in both the training and validation sets.

**Reasoning**: To combine the extracted color, texture, and shape features, I will use `np.concatenate` along `axis=1` (horizontally) for both training and validation sets as per the instructions, and then print the shapes of the resulting combined feature vectors.

```
import numpy as np

# 1. Concatenate train_color_features, train_texture_features, and
train_shape_features
X_train_combined = np.concatenate((train_color_features,
train_texture_features, train_shape_features), axis=1)

# 2. Concatenate val_color_features, val_texture_features, and
val_shape_features
X_val_combined = np.concatenate((val_color_features,
val_texture_features, val_shape_features), axis=1)
```

```
# 3. Print the shapes of the resulting combined feature vectors
print(f"Shape of X_train_combined: {X_train_combined.shape}")
print(f"Shape of X_val_combined: {X_val_combined.shape}")
```

```
Shape of X_train_combined: (4180, 56)
Shape of X_val_combined: (1044, 56)
```

# Address Class Imbalance (Training Data)

## Subtask:

Apply appropriate techniques to mitigate the class imbalance in the feature-engineered training dataset.

```
from imblearn.over_sampling import SMOTE

# Train and Evaluate Logistic Regression Model

## Subtask:

Train a Logistic Regression classifier using the feature-engineered and imbalance-addressed training data. Evaluate its performance on the validation set using metrics such as accuracy, precision, recall, F1-score, and a confusion matrix.

**Reasoning**: To train and evaluate the Logistic Regression model as per the subtask, I need to import the required libraries, instantiate the model, train it on the resampled training data, make predictions on the validation set, and then calculate and visualize the specified evaluation metrics.

```
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score, precision_score,
recall_score, f1_score, confusion_matrix, classification_report
import matplotlib.pyplot as plt
import seaborn as sns
import numpy as np
import tensorflow as tf # Added for robustness with
tf.keras.utils.image_dataset_from_directory

# Get class names if not already in scope (from cell 8413c747)
# Assuming class_names is available from previous execution. If not,
reload train_ds and extract.
if 'class_names' not in globals():
    # This block should ideally not be needed if previous cells were
run sequentially
    # but included for robustness if running this cell in isolation.
    dataset_path = '/content/gdrive/MyDrive/Medicinal Leaf dataset'
    IMG_HEIGHT = 224
    IMG_WIDTH = 224
    BATCH_SIZE = 32
    train_ds_temp = tf.keras.utils.image_dataset_from_directory(
        dataset_path,
        validation_split=0.2,
        subset="training",
        seed=123,
        image_size=(IMG_HEIGHT, IMG_WIDTH),
        batch_size=BATCH_SIZE
    )
    class_names = train_ds_temp.class_names

# 1. Instantiate LogisticRegression model
# Set max_iter to a sufficiently large number to ensure convergence
log_reg_model = LogisticRegression(random_state=42, max_iter=1000,
solver='liblinear', multi_class='ovr')
# Using 'liblinear' solver which handles L1/L2 penalties and is good
for small datasets, and 'ovr' for multi-class.
```

```python
# 2. Train the model using the resampled training data

# Task

Train and evaluate Support Vector Machine (SVM) and Random Forest models using the feature-engineered and imbalance-addressed training data. Compare the performance of these models, along with the Logistic Regression model, using accuracy, precision, recall, F1-score, and confusion matrices. Finally, summarize the findings, discussing the effectiveness of features, comparative model performance, and insights gained, and suggest next steps.

## Train and Evaluate Support Vector Machine (SVM) Model

### Subtask:

Train a Support Vector Machine (SVM) classifier using the feature-engineered and imbalance-addressed training data. Evaluate its performance on the validation set using metrics such as accuracy, precision, recall, F1-score, and a confusion matrix.

**Reasoning**: To train and evaluate the SVM model as per the subtask, I need to import the required libraries, instantiate the model, train it on the resampled training data, make predictions on the validation set, and then calculate and visualize the specified evaluation metrics.

## Train and Evaluate Support Vector Machine (SVM) Model

### Subtask:

Train a Support Vector Machine (SVM) classifier using the feature-engineered and imbalance-addressed training data. Evaluate its performance on the validation set using metrics such as accuracy, precision, recall, F1-score, and a confusion matrix.

# Train and Evaluate Random Forest Model

## Subtask:

Train a Random Forest classifier using the feature-engineered and imbalance-addressed training data. Evaluate its performance on the validation set using metrics such as accuracy, precision, recall, F1-score, and a confusion matrix.

# Task

Compare the performance of the Logistic Regression, Support Vector Machine (SVM), and Random Forest models using bar charts for key performance metrics (accuracy, precision, recall, and F1-score) on the validation set, including clear legends for each model. Additionally, provide a comprehensive summary of the project's findings, covering the effectiveness of the extracted features (color, texture, shape), the comparative performance of the different machine learning models, and overall insights derived from the dataset and classification challenge, along with suggestions for future improvements.

# Compare Model Performance

## Subtask:

Generate visualizations, such as bar charts comparing key performance metrics (accuracy, precision, recall, F1-score) and confusion matrices, for all trained models (Logistic Regression, SVM, and Random Forest). Ensure all visualizations include clear legends to aid interpretation.

```
import matplotlib.pyplot as plt
import pandas as pd
import numpy as np

# 1. Collect Metrics from previous cell outputs
# Logistic Regression (from cell 3609e3ad or 55139684)
log_reg_metrics = {
    'Accuracy': 0.3103,
    'Precision': 0.3166,
    'Recall': 0.3103,
    'F1-Score': 0.2889
}

# SVM (from cell 0e753d69)
svm_metrics = {
    'Accuracy': 0.3554,
    'Precision': 0.3728,
    'Recall': 0.3554,
    'F1-Score': 0.3403
}

# Random Forest (from cell 6PwDtMr8RZyX)
# Note: For Random Forest, 'acc' is micro avg. For precision, recall,
f1, using weighted avg from report.
random_forest_metrics = {
    'Accuracy': 0.1216,
    'Precision': 0.20, # weighted avg from classification report
    'Recall': 0.12,  # weighted avg from classification report
    'F1-Score': 0.11   # weighted avg from classification report
}

# 2. Store these metrics in a DataFrame for easy comparison
metrics_df = pd.DataFrame({
    'Logistic Regression': log_reg_metrics,
    'SVM': svm_metrics,
    'Random Forest': random_forest_metrics
})

print("Model Performance Metrics:")
print(metrics_df.round(4))
```

```python
# 3. Create a helper function to plot bar charts for each metric
def plot_metric_comparison(metric_name, df):

# Task

To continue, I will first re-run the interrupted feature extraction process from `8e90c6d9` to ensure all features are correctly extracted. Then, I will scale the combined features using `StandardScaler`, apply `PCA` to reduce dimensionality, and finally address class imbalance using `SMOTE` on the PCA-transformed training data, storing the results in `X_train_pca`, `X_val_pca`, `X_train_resampled`, and `y_train_resampled`.

```
import cv2
import numpy as np
import tensorflow as tf
from skimage.feature import graycomatrix, graycoprops
from skimage.color import rgb2gray
from sklearn.preprocessing import StandardScaler
from sklearn.decomposition import PCA
from imblearn.over_sampling import SMOTE
from collections import Counter
```

```python
import matplotlib.pyplot as plt

# Task

The previous code cell was successfully executed, confirming the re-extraction, scaling, PCA transformation, and SMOTE resampling of the color, texture, and shape features.

The next step in the overall plan is to **Develop Advanced Descriptors**, specifically researching and implementing techniques for vein topology extraction (e.g., skeletonization, graph-based methods) and leaf margin entropy calculation (e.g., fractal dimension, contour analysis) to capture more subtle and discriminative characteristics of the medicinal leaves. These advanced descriptors will then be integrated into the feature extraction pipeline.

## Develop Advanced Descriptors

### Subtask:

Implement functions to extract vein topology features using skeletonization and leaf margin fractal dimension using box-counting from images, and then apply these functions to the training and validation datasets.

**Reasoning**: The subtask requires implementing two new feature extraction functions, `extract_vein_features` (using skeletonization for vein topology) and `calculate_margin_fractal_dimension` (using box-counting for leaf margin fractal dimension), and then applying these to the `train_images` and `val_images` datasets. The previous markdown block (`f230b9f8`) provides a comprehensive setup for reloading data and pre-existing feature extraction, which I will include to ensure all necessary data and previous features are correctly established before adding the new functions.

```python
import cv2
import numpy as np
import tensorflow as tf
from skimage.feature import graycomatrix, graycoprops
from skimage.color import rgb2gray
from sklearn.preprocessing import StandardScaler
from sklearn.decomposition import PCA
from imblearn.over_sampling import SMOTE
from collections import Counter
import matplotlib.pyplot as plt

# New imports for vein/fractal features

# Extract CNN Embeddings

## Subtask:

Utilize a pre-trained Convolutional Neural Network (CNN) model (e.g., VGG16, ResNet50) to extract high-level feature embeddings from each image in the dataset.

**Reasoning**: The subtask requires extracting CNN embeddings from the images. I will use a pre-trained MobileNetV2 model without its top layer, preprocess the existing NumPy image arrays, extract the features, flatten them, and store them as `train_cnn_embeddings` and `val_cnn_embeddings`.

```
import tensorflow as tf
import numpy as np

# 1. Choose a pre-trained CNN model (MobileNetV2) and load without top
layer
# Using MobileNetV2 for a balance of performance and speed
```

```python
print("Loading pre-trained MobileNetV2 model...")
base_model = tf.keras.applications.MobileNetV2(
    input_shape=(IMG_HEIGHT, IMG_WIDTH, 3),
    include_top=False,
    weights='imagenet'
)

# 2. Make the base model non-trainable
base_model.trainable = False

# 3. Preprocess the images according to the model's requirements
# MobileNetV2 expects input in the range [-1, 1]
# train_images and val_images are currently in [0, 255]

# Apply preprocessing to training images
print("Preprocessing training images...")
processed_train_images =
tf.keras.applications.mobilenet_v2.preprocess_input(train_images)

# Apply preprocessing to validation images
print("Preprocessing validation images...")
processed_val_images =
tf.keras.applications.mobilenet_v2.preprocess_input(val_images)

# 4. Extract features (embeddings) from the preprocessed images
print("Extracting CNN embeddings from training images...")
train_cnn_embeddings_raw = base_model.predict(processed_train_images)

print("Extracting CNN embeddings from validation images...")
val_cnn_embeddings_raw = base_model.predict(processed_val_images)

# 5. Flatten the extracted CNN embeddings
# The output of base_model.predict will have a shape like (num_images,
height, width, channels)
# We need to flatten the (height, width, channels) part for each image
train_cnn_embeddings =
train_cnn_embeddings_raw.reshape(train_cnn_embeddings_raw.shape[0], -
1)
val_cnn_embeddings =
val_cnn_embeddings_raw.reshape(val_cnn_embeddings_raw.shape[0], -1)

# 6. Print the shapes of the resulting embeddings to verify
print(f"Shape of train_cnn_embeddings: {train_cnn_embeddings.shape}")
print(f"Shape of val_cnn_embeddings: {val_cnn_embeddings.shape}")

# Implement Hybrid Feature Fusion

## Subtask:

Develop a hybrid feature fusion framework that combines the previously extracted handcrafted descriptors (color, texture, shape, and newly developed advanced descriptors) with the CNN embeddings.

**Reasoning**: To develop the hybrid feature fusion framework, I will concatenate all the previously extracted handcrafted features (color, texture, shape, vein, fractal) and the CNN embeddings for both the training and validation datasets into single fused feature vectors, and then print their shapes to verify the fusion.

```

# Research Few-Shot Learning

## Subtask:

Investigate few-shot learning techniques suitable for image classification tasks, especially those that can leverage engineered feature representations.

# Research Few-Shot Learning

## Subtask:

Investigate few-shot learning techniques suitable for image classification tasks, especially those that can leverage engineered feature representations.

### Instructions

1. Understand the core problem and motivation behind few-shot learning in the context of image classification with limited data per class.
2. Research and familiarize yourself with prominent few-shot learning approaches. Focus on understanding the concepts, architectures, and advantages/disadvantages of:
   - **Prototypical Networks**
   - **Siamese Networks**
   - **Meta-Learning (e.g., MAML)**
3. Consider how these techniques can leverage the already extracted and fused feature representations (both handcrafted and CNN embeddings). Think about which approach might be most suitable for incorporating these rich feature vectors.
4. Select a specific few-shot learning technique that appears most promising for implementation in the next step, based on your research and its compatibility with the current feature engineering pipeline.

## Few-Shot Learning Research

### 1. Core Problem and Motivation:

Few-shot learning (FSL) addresses the challenge of building accurate machine learning models when only a very small number of labeled examples are available for each class during training. This is highly relevant in image classification for medicinal leaves, where new species might be discovered, or rare diseases identified, for which extensive datasets are difficult or impossible to obtain. Traditional supervised learning models typically require large datasets to generalize well, which FSL aims to overcome by learning to learn, or by learning similarity metrics.

### 2. Prominent Few-Shot Learning Approaches:

- **Prototypical Networks:**
  - **Concept:** These networks learn a metric space where samples from each class cluster around a single 'prototype' representation. During inference, the class of a new query image is determined by finding the closest prototype in this learned space.

  - **Architecture:** Typically consists of an embedding function (e.g., a CNN) that maps input images into a lower-dimensional feature space. Prototypes are computed as the mean of the support set embeddings for each class.
  - **Advantages:** Simple to understand and implement, computationally efficient during inference, and can generalize well to new classes not seen during training.
  - **Disadvantages:** Sensitive to the choice of distance metric and the quality of the embedding space. May struggle with classes that have high intra-class variance.
- **Siamese Networks:**
  - **Concept:** Siamese networks consist of two identical subnetworks (sharing weights) that process two input images simultaneously. The goal is to learn an embedding where semantically similar inputs are mapped close together, and dissimilar inputs are mapped far apart. This is achieved by training with pairs of images and a loss function that encourages this behavior (e.g., contrastive loss or triplet loss).
  - **Architecture:** Two identical CNNs feed into a distance metric (e.g., Euclidean distance) followed by a classification layer for similarity prediction.
  - **Advantages:** Excellent for learning similarity functions, useful for verification tasks (e.g., is this image X or not?), and robust to variations when trained on diverse pairs.
  - **Disadvantages:** Training can be complex due to pair/triplet generation, and inference requires comparing a query to all support set images, potentially increasing computation time for many classes.
- **Meta-Learning (e.g., MAML - Model-Agnostic Meta-Learning):**
  - **Concept:** Meta-learning algorithms aim to train a model to quickly adapt to new tasks (new classes in FSL). MAML learns a good initialization for a model's parameters such that a few gradient descent steps on a new task's support set lead to strong performance on that task's query set.
  - **Architecture:** Involves an inner loop (task-specific learning with few examples) and an outer loop (meta-learning across many tasks). The base model itself is typically a CNN.
  - **Advantages:** Highly flexible as it can be applied to almost any model architecture, learns to adapt rapidly with minimal new data.
  - **Disadvantages:** Computationally intensive to train, requires careful hyperparameter tuning, and can be sensitive to the choice of optimization algorithms.

### 3. Leveraging Fused Feature Representations:

The existing pipeline generates a rich fused feature vector (`X_train_fused`, `X_val_fused`) that combines handcrafted features (color, texture, shape, vein, fractal) and CNN embeddings (from MobileNetV2). These are already a powerful, lower-dimensional representation of the images.

- **Prototypical Networks:** This approach is highly compatible. The `X_train_fused` and `X_val_fused` can directly serve as the embedding space. We would compute prototypes (mean of features) for each class in the support set and classify query images based on distance to these prototypes. This eliminates the need to train a

new CNN for embedding, as the MobileNetV2 embeddings are already part of our fused features.

- **Siamese Networks:** This would involve using a simple neural network head (e.g., a few dense layers) that takes two fused feature vectors as input and learns a similarity score. The core embedding generation (the fused features) is already done. This could work well, but it might require a custom training loop to manage pairs.
- **Meta-Learning (MAML):** While powerful, MAML is generally applied when training the *entire* model, including the feature extractor. Since our features are already extracted and fixed (due to `base_model.trainable = False` for CNN embeddings), applying MAML directly to the fused features might be less straightforward or less impactful than using it for end-to-end learning.

### 4. Selected Few-Shot Learning Technique for Implementation:

**Prototypical Networks** appear to be the most promising and straightforward choice for the next implementation step.

**Reasoning:**

- **Direct Compatibility:** The fused feature vectors (`X_train_fused`, `X_val_fused`) are already high-quality embeddings. Prototypical Networks can directly leverage these vectors as their embedding space, avoiding the need to retrain complex neural networks.
- **Simplicity and Efficiency:** The core logic of Prototypical Networks (calculate mean for prototypes, measure Euclidean distance for classification) is simple to implement and computationally efficient, making it suitable for a proof-of-concept with our existing feature pipeline.
- **Explicit Class Prototypes:** The concept of explicit class prototypes aligns well with the idea of distinct medicinal leaf categories, where each class should ideally have a central, representative feature vector.
- **Avoids Complex Training:** Unlike Siamese networks (which need careful pair sampling) or MAML (which requires a meta-training setup), Prototypical Networks can be directly applied to the extracted features for few-shot classification with minimal additional training complexity beyond feature extraction.

Therefore, we will proceed with implementing a Prototypical Network-like approach using our `X_train_fused` and `X_val_fused` feature vectors.

# Implement Few-Shot Learning Model

## Subtask:

Implement a selected few-shot learning model (Prototypical Network) using the hybrid feature-fused dataset.

# Final Task

## Subtask:

Summarize the entire process, including the development of new descriptors, the hybrid feature fusion framework, and the results of the few-shot learning experiment. Discuss the effectiveness of these advanced techniques in improving classification performance and recognizing unseen plant types.

# Summary:

## Data Analysis Key Findings

- **Comprehensive Feature Fusion**: The process successfully re-extracted and fused a diverse set of features, including color (27 features), texture (24 features), shape (5 features), newly developed vein topology (2 features), and fractal dimension (1 feature), along with high-level CNN embeddings (62720 features). This resulted in fused feature vectors of 62,779 dimensions for both training and validation sets.
- **Feature Preprocessing for Few-Shot Learning**: The fused features were preprocessed by applying `StandardScaler` for normalization and `PCA` for dimensionality reduction. PCA retained 95% of the variance, reducing the feature dimensionality to 523, resulting in `X_train_few_shot` and `X_val_few_shot` for the few-shot learning task.
- **Prototypical Network Implementation**: A `generate_few_shot_task` function was successfully implemented to create episodic tasks (e.g., 5-way, 1-shot with 5 query samples per class). The `prototypical_network_predict` function calculates class prototypes as the mean of support set features and classifies query samples based on their Euclidean distance to these prototypes.
- **Few-Shot Learning Performance**: The implemented Prototypical Network achieved an average accuracy of approximately 0.6120 over 1000 randomly generated 5-way, 1-shot tasks on the validation data.

## Insights or Next Steps

- The successful integration of diverse handcrafted features and CNN embeddings into a hybrid representation, followed by dimensionality reduction, provides a robust foundation for few-shot learning tasks. This approach appears promising for classifying new, unseen medicinal leaf types with limited examples.
- Further optimization of the few-shot learning model could involve experimenting with different N-way, K-shot configurations, exploring other distance metrics within the Prototypical Network, or fine-tuning the PCA components to potentially enhance classification accuracy.
